When it comes to Global Feature Descriptors (i.e feature vectors that quantify an image), there are three major attributes to be considered – Color, Shape and Texture. These three could be used separately or combined to quantify images. In this tutorial, we will learn how to recognize texture in images. We will study a new type of global feature descriptor called Haralick Texture. Let's jump right into it!

Objectives

- 1 How to label and organize our own dataset?
- 2 What is Haralick Texture and how it is computed?
- 3 How to use Haralick Texture module in mahotas library?
- 4 How to recognize textures in images?
- 5 How to use Linear SVM to train and classify images?
- 6 How to make predictions using the created model on an unseen data?

What is a Texture?

Texture defines the consistency of patterns and colors in an object/image such as bricks, school uniforms, sand, rocks, grass etc. To classify objects in an image based on texture, we

have to look for the consistent spread of patterns and colors in the object's surface. Rough-Smooth, Hard-Soft, Fine-Coarse are some of the texture pairs one could think of, although there are many such pairs.

What is Haralick Texture?

Haralick Texture is used to quantify an image based on texture. It was invented in 1973 and you can read about it in detail [here](#). The fundamental concept involved in computing Haralick Texture features is the Gray Level Co-occurrence Matrix (GLCM).

What is GLCM?

Gray Level Co-occurrence matrix (GLCM) uses adjacency concept in image processing. The basic idea is that it looks for pairs of adjacent pixel values that occur in an image and counts the number of times they occur over the entire image. Below figure explains how a GLCM is constructed.

- Load the training dataset
- Extract features function
- Extract features for all images
- Create the machine learning classifier
- Test the classifier on testing

Figure 1. Gray Level Co-occurrence Matrix (GLCM)

As you can see from the above image, gray-level pixel value 1 and 2 occurs twice in the image and hence GLCM records it as two. But pixel value 1 and 3 occurs only once in the image and thus GLCM records it as one. Of course, I have assumed the adjacency calculation only from left-to-right. Actually, there are four types of adjacency and hence four GLCM matrices are constructed for a single image. Four types of adjacency are as follows.

- Left-to-Right

- Top-to-Bottom
- Top Left-to-Bottom Right
- Top Right-to-Bottom Left

Haralick Texture Feature Vector

From the four GLCM matrices, 14 textural features are computed that are based on statistical theory. All these 14 statistical features need a separate blog post to read in detail about those [here](#). Normally, the feature vector is taken to be 14th dim. Computing 14th dim might increase the computational time.

Implementing Texture Recognition

Ok, let's start with the code!

Actually, it will take just 10–15 minutes to complete our texture recognition system using OpenCV, Python, sklearn and mahotas provided we have the training dataset.

Note: In case if you don't have these packages installed, feel free to install these using my [environment setup posts](#) given below.

- Deep Learning Environment Setup (Windows)
- Deep Learning Environment Setup (Linux)

- Import the necessary packages
- Load the training dataset
- Extract features function
- Extract features for all images
- Create the machine learning classifier
- Test the classifier on testing

Import the necessary packages

train_test.py

```
1 import cv2
2 import numpy as np
3 import os
4 import glob
5 import mahotas as mt
6 from sklearn.svm import LinearSVC
```

Load the training dataset

train_test.py

```
1 # load the training dataset
2 train_path = "dataset/train"
3 train_names = os.listdir(train_path)
4
5 # empty list to hold feature vectors and train labels
6 train_features = []
7 train_labels = []
```

- Line 2 is the path to training dataset.
- Line 3 gets the class names of the training data.
- Line 6–7 are empty lists to hold feature vectors and labels.

Extract features function

train_test.py

```
1 def extract_features(image):
2     # calculate haralick texture features for 4 types of adjacency
3     textures = mt.features.haralick(image)
4
5     # take the mean of it and return it
6     ht_mean = textures.mean(axis=0)
7     return ht_mean
```

- Line 1 is a function that takes an input image to compute haralick texture.
- Line 3 extracts the haralick features for all 4 types of adjacency.
- Line 6 finds the mean of all 4 types of GLCM.
- Line 7 returns the resulting feature vector for that image which describes the texture.

Extract features for all images

train_test.py

code

```
1 # loop over the training dataset
2 print "[STATUS] Started extracting haralick textures.."
3 for train_name in train_names:
4     cur_path = train_path + "/" + train_name
5     cur_label = train_name
6     i = 1
7
```

```

8         for file in glob.glob(cur_path + "/*.jpg"):
9             print "Processing Image - {} in {}".format(i, cur_label)
10            # read the training image
11            image = cv2.imread(file)
12
13            # convert the image to grayscale
14            gray = cv2.cvtColor(image, cv2.COLOR_BGR2GRAY)
15
16            # extract haralick texture from the image
17            features = extract_features(gray)
18
19            # append the feature vector and label
20            train_features.append(features)
21            train_labels.append(cur_label)
22
23            # show loop update
24            i += 1

```

- Line 4 loops over the training labels we have just included from training directory.
- Line 5 is the path to current image class directory.
- Line 6 holds the current image class label.
- Line 8 takes all the files with .jpg as the extension and loops through each file one by one.
- Line 11 reads the input image that corresponds to a file.
- Line 14 converts the image to grayscale.
- Line 17 extracts haralick features for the grayscale image.
- Line 20 appends the 13-dim feature vector to the training features list.
- Line 21 appends the class label to training classes list.

train_test.py

code

```
1 # have a look at the size of our feature vector and labels
2 print "Training features: {}".format(np.array(train_features).shape)
3 print "Training labels: {}".format(np.array(train_labels).shape)
```

Create the machine learning classifier

train_test.py

```
1 # create the classifier
2 print "[STATUS] Creating the classifier.."
3 clf_svm = LinearSVC(random_state=9)
4
5 # fit the training data and labels
6 print "[STATUS] Fitting data/label to model.."
7 clf_svm.fit(train_features, train_labels)
```

- Line 3 creates the Linear Support Vector Machine classifier.
- Line 7 fits the training features and labels to the classifier.

Test the classifier on testing data

train_test.py

```
1
2 # loop over the test images
3 test_path = "dataset/test"
4 for file in glob.glob(test_path + "/*.*"):
```

9     gray = cv2.cvtColor(image, cv2.COLOR_BGR2GRAY)
10
11    # extract haralick texture from the image
12    features = extract_features(gray)
13
14    # evaluate the model and predict label
15    prediction = clf_svm.predict(features.reshape(1, -1))[0]
16
17    # show the label
18    cv2.putText(image, prediction, (20,30), cv2.FONT_HERSHEY_SIMPLE
19
20    # display the output image
21    cv2.imshow("Test_Image", image)
22    cv2.waitKey(0)

```

- Line 2 gets the testing data path.
- Line 3 takes all the files with the .jpg extension and loops through each file one by one.
- Line 5 reads the input image.
- Line 8 converts the input image into grayscale image.
- Line 11 extract haralick features from grayscale image.
- Line 14 predicts the output label for the test image.
- Line 17 displays the output class label for the test image.
- Finally, Line 20 displays the test image with predicted label.

Training images

These are the images from which we train our machine learning classifier to learn texture features. You can collect the images of your choice and include it under a label. For example, “Grass” images are collected and stored inside a folder named “grass”. They can either be taken from a simple google search (easy to do; but our model won't generalize well) or from your own camera/smart-phone (which is indeed time-consuming but our model could generalize well due to real-world images).

As a demonstration, I have included my own training and testing images. I have a folder named training images which holds 3 images per class. Training images with their class/label are shown below.

Figure 2. Training Images

Testing images

These could be images or a video sequence from a smartphone/camera. We will use this test data so that our model performs feature extraction on it and tries to come up with the best possible label/class.

Some of the test images for which we need to predict the class/label are shown below.

Note: These test images won't have any label associated with them. Our purpose is to predict the best possible label/class for the image it sees.

If you *copy-paste* the above code in any of your directory and run `python train_test.py`, you will get the following results.

Thus, we have implemented our very own Texture Recognition system using Haralick Textures, Python and OpenCV.
